Beta (B.1.351)–variant coronavirus disease 2019 (COVID-19) disease was investigated in Qatar. Compared with the Alpha (B.1.1.7) variant, odds (95% confidence interval) of progressing to severe disease, critical disease, and COVID-19–related death were 1.24-fold (1.11–1.39), 1.49-fold (1.13–1.97), and 1.57-fold (1.03–2.43) higher, respectively, for the Beta variant.

**Keywords.** SARS-CoV-2; variant; infection; severe disease; epidemiology.

Commencing in mid-January 2021, Qatar experienced a severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) Alpha [1] (B.1.1.7)–variant wave that peaked in the first week of March [2–5], but was immediately followed by a Beta [1] (B.1.351)–variant wave that peaked in the first week of April [2–6]. This created a unique epidemiologic situation that allowed comparative assessment of the severity, criticality, and fatality of these 2 variants.

Received 1 August 2021; editorial decision 13 October 2021; published online 17 October 2021.

## METHODS

We investigated severity (acute-care hospitalization) [7], criticality (intensive care unit [ICU] hospitalization) [7], and fatality [8] of both variants through 8 case-control studies applied to the complete national cohorts of SARS-CoV-2 infections, coronavirus disease 2019 (COVID-19) disease cases, and COVID-19–related deaths in Qatar, a country with diverse demographics where 89% of the population comprises expatriates from over 150 countries [9]. Data on polymerase chain reaction (PCR) testing and clinical characteristics were extracted from the national federated COVID-19 databases that have captured all SARS-CoV-2–related data since the start of the epidemic. These databases were retrieved from the integrated nationwide digital-health information platform (universal healthcare system), and include all records of PCR testing, antibody testing, vaccinations, COVID-19 hospitalizations, infection severity classification, and COVID-19–related deaths. Databases are complete at the national level with no missing information.

Records of PCR testing and clinical data for hospitalized patients with COVID-19 were examined. Details of the laboratory methods for PCR testing are found in [Supplementary Text 1](#). Each person who had a PCR-positive test result and hospital admission was subject to an infection-severity assessment every 3 days until discharge or death. Individuals who progressed to COVID-19 disease between the time of the PCR-positive test result and the end of the study were classified based on their worst outcome, starting with death [8], followed by critical disease [7], and then severe disease [7].

Cases in the case-control studies were persons who progressed to COVID-19 severe disease, critical disease, or death. Controls were persons with asymptomatic or mild SARS-CoV-2 infections. Cases and controls were matched at a ratio of 1:3 by 10-year age group, sex, and biweekly interval of the PCR diagnosis date. Every case in Qatar that met the inclusion criteria and that could be matched to a control was included in the study. Classification of case severity, criticality, and fatality followed the World Health Organization guidelines [7, 8], and assessments were made by trained medical personnel through individual chart reviews. Details of the COVID-19 severity, criticality, and fatality classification are found in [Supplementary Text 2](#).

From 18 January until 15 February 2021, the Alpha-variant wave expanded rapidly and weekly rounds of viral genome sequencing [2–5] of randomly collected samples confirmed the presence of this and other originally circulating “wild-type” variants, but documented only limited presence of the Beta variant and no other variants of concern [2–5]. This allowed a comparative assessment for the Alpha variant versus wild-type variants

during this specific time frame (Supplementary Text 3). From 8 March through 31 May 2021, the Beta-variant wave expanded rapidly and viral genome sequencing [2–5] and multiplex quantitative reverse-transcription PCR (RT-qPCR) variant screening [2–6] indicated dominance of the Beta and Alpha variants, with limited presence of other variants [2–6]. This enabled comparisons between the Beta versus Alpha variants during this specific time frame (Supplementary Text 3). The Delta [1] (B.1.617.2) variant has been introduced more recently in Qatar, and it remains at a low incidence as of 11 July 2021 [4–6]. Further details on the classification of infections by variant type are found in Supplementary Text 3.

Descriptive statistics (frequency distributions and measures of central tendency) were used to characterize the study samples. Two-sided *P* values of less than .05 were considered statistically significant. Odds ratios and their associated 95% confidence intervals (CIs) were calculated using the exact method. Confidence intervals were not adjusted for multiplicity. Interactions were not investigated. Two sensitivity analyses were conducted by first adjusting for age, and second by adjusting for age and sex, in logistic regression analyses. Statistical analyses were conducted in STATA/SE version 17.0 (StataCorp).

The study was approved by the Hamad Medical Corporation and Weill Cornell Medicine–Qatar Institutional Review Boards with waiver of informed consent. Reporting of the study followed the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guidelines (Supplementary Table 1).

## RESULTS

Demographic characteristics of the samples for each disease outcome in assessing the severity, criticality, and fatality of the Alpha variant compared with the wild-type variants are presented in Supplementary Table 2. Compared with wild-type variants, the odds of progressing to severe disease were 1.48-fold (95% CI: 1.18–1.84-fold) higher for the Alpha variant (Table 1). The odds of progressing to critical disease were 1.58-fold (95% CI: .79–3.10-fold) higher, but did not reach statistical significance, perhaps because of the small number of critical disease cases. There were also too few COVID-19–related deaths to assess the fatality of the Alpha variant.

The median time from PCR-positive test to severe disease was 7 days (mean: 7 days; interquartile range [IQR]: 4–9 days) for Alpha cases and 6 days (mean: 6 days; IQR: 3–8 days) for wild-type cases. The median time from severe to critical disease was 4 days (mean: 5 days; IQR: 3–7 days) for Alpha cases and 4 days (mean: 6 days; IQR: 3–7 days) for wild-type cases. There were too few deaths in this analysis to provide summary statistics.

Demographic characteristics of the samples for each disease outcome in assessing the severity, criticality, and fatality of the Beta variant compared with the Alpha variant are presented in Supplementary Table 3. Compared with the Alpha variant, the odds of progressing to severe disease were 1.24-fold (95% CI: 1.11–1.39-fold) higher for the Beta variant (Table 1). The odds of progressing to critical disease were 1.49-fold (95% CI: 1.13–1.97-fold) higher, and the odds of COVID-19–related death were 1.57-fold (95% CI: 1.03–2.43-fold) higher.

**Table 1. Infection Severity, Criticality, and Fatality of the Alpha and Beta Variants in the Population of Qatar**

Groups	Infection Severity <sup>a</sup>	Assessment of Severity, Criticality, and Fatality of the Alpha Variant Compared With the Wild-type Variants Circulating Between 18 January and 15 February 2021 <sup>b</sup>			Assessment of Severity, Criticality, and Fatality of the Beta Variant Compared With the Alpha Variant Between 8 March and 31 May 2021 <sup>c</sup>		
		Infection With an Alpha Variant	Infection With a Wild-type Variant	Odds Ratio (95% CI)	Infection With a Beta Variant	Infection With an Alpha Variant	Odds Ratio (95% CI)
Cases	Severe disease	188	279	1.48 (1.18–1.84)	2036	483	1.24 (1.11–1.39)
Controls	Asymptomatic or mild infection	431	944		5806	1707	
Cases	Critical disease	21	37	1.58 (.79–3.10)	382	81	1.49 (1.13–1.97)
Controls	Asymptomatic or mild infection	49	125		1056	333	
Cases	Severe or critical disease	209	316	1.45 (1.18–1.79)	2418	564	1.28 (1.15–1.42)
Controls	Asymptomatic or mild infection	480	1054		6764	2019	
Cases	COVID-19–related death	2	9	.83 (.07–5.58)	142	37	1.57 (1.03–2.43)
Controls	Asymptomatic or mild infection	7	26		381	156	

Cases and controls were matched on a ratio of 1:3 by 10-year age group, sex, and biweekly interval of the PCR diagnosis date.

Abbreviations: CI, confidence interval; COVID-19, coronavirus disease 2019; PCR, polymerase chain reaction; SARS-CoV-2, severe acute respiratory syndrome coronavirus 2.

<sup>a</sup>Severe disease, critical disease, and COVID-19–related death were defined based on the World Health Organization criteria for classifying SARS-CoV-2 infection severity [7] and COVID-19–related death [8].

<sup>b</sup>From 18 January to 15 February 2021, the Alpha variant and other wild-type variants dominated incidence, with limited presence of the Beta variant [2–5].

<sup>c</sup>From 8 March to 31 May 2021, the Beta and Alpha variants dominated incidence, with limited presence of other variants [2–6].

**Figure 1.** Number of (A) daily new COVID-19 acute-care hospital admissions, (B) daily new COVID-19 ICU hospital admissions, and (C) COVID-19–related deaths in Qatar. Abbreviations: COVID-19, coronavirus disease 2019; ICU, intensive care unit.

The median time from PCR-positive test to severe disease was 5 days (mean: 5 days; IQR: 3–8 days) for Beta cases and 5 days (mean: 6 days; IQR: 3–8 days) for Alpha cases. The median time from severe to critical disease was 7 days (mean: 9 days; IQR: 4–11 days) for Beta cases and 7 days (mean: 10 days; IQR: 4–14 days) for Alpha cases. The median time from critical disease to death was 15 days (mean: 20 days; IQR: 6–26 days) for Beta cases and 15 days (mean: 21 days; IQR: 6–32 days) for Alpha cases.

Sensitivity analyses confirmed the above results (Supplementary Table 4).

## DISCUSSION

The Alpha variant presented a 48% higher risk of severe disease than wild-type variants in the population of Qatar, affirming its greater gravity [10, 11] (odds ratio approximates risk ratio

for rare outcomes). Infection with the Beta variant was associated with even greater risks of severe and critical disease and COVID-19–related death, affirming earlier observational analyses suggesting its high gravity [11, 12]. Compared with the Alpha variant, infections with the Beta variant posed a 24% higher risk of severe disease, 49% higher risk of critical disease, and 57% higher risk of COVID-19–related death.

These results explain the changing pattern of hospitalizations and deaths seen during the Beta wave compared with the Alpha wave (Figure 1). Acute-care admissions doubled during the Beta wave, but ICU admissions and deaths quadrupled, with the disproportionately greater effect of this variant on critical disease and COVID-19–related death.

Limitations include the smaller sample sizes of critical disease and COVID-19–related deaths in the Alpha-variant analysis (Supplementary Table 2) compared with the Beta-variant analysis (Supplementary Table 3), as COVID-19 criticality

and fatality have been low in Qatar's predominantly young and working-age population [9, 13], leading to statistically nonsignificant results and wider 95% CIs. Data on comorbid conditions were not available to study investigators; hence, they could not be explicitly factored in our analysis. Nevertheless, matching and adjusting for age in analysis may have served as a proxy, given that comorbidities are associated with old age. Furthermore, with the young population structure [9], we anticipate that only a small proportion of the study population may have had serious comorbid conditions. However, our findings may not be entirely generalizable to other settings, where elderly people constitute a sizable proportion of the population. Imperfect assay sensitivity and specificity of PCR testing may have affected infection ascertainment. However, all PCR testing was performed with extensively used, investigated, and validated commercial platforms having essentially 100% sensitivity and specificity (Supplementary Text 1). Unlike blinded randomized clinical trials, the investigated observational cohorts were neither blinded nor randomized.

In conclusion, the Alpha variant is associated with a 48% higher risk of severe disease than wild-type variants. In turn, the Beta variant is associated with a 24% higher risk of severe disease than the Alpha variant, and strikingly, an even higher risk of critical disease (49%) and COVID-19-related death (57%). These findings highlight risks to healthcare systems, particularly intensive care facilities and resources, in the event of a globally increased circulation of the Beta variant. With the Delta variant increasingly dominating incidence in Qatar and other countries, an extension of this work could be a comparison of disease outcomes of Delta versus Alpha and Beta infections.

### Supplementary Data

Supplementary materials are available at *Clinical Infectious Diseases* online. Consisting of data provided by the authors to benefit the reader, the posted materials are not copyedited and are the sole responsibility of the authors, so questions or comments should be addressed to the corresponding author.

### Notes

**Author contributions.** L. J. A. conceived and co-designed the study, led the statistical analyses, and co-wrote the first draft of the article. H. C. co-designed the study, performed the statistical analyses, and co-wrote the first draft of the article. All authors contributed to data collection and acquisition, database development, discussion and interpretation of the results, and to the writing of the manuscript. All authors have read and approved the final manuscript.

**Acknowledgments.** The authors acknowledge the many dedicated individuals at Hamad Medical Corporation, the Ministry of Public Health, the Primary Health Care Corporation, the Qatar Biobank, and Sidra Medicine for their diligent efforts and contributions to make this study possible. The dataset of this study is a property of the Qatar Ministry of Public Health that was provided to the researchers through a restricted-access agreement that

prevents sharing the dataset with a third party or publicly. Aggregate data are available within the manuscript and its [Supplementary Material](#). A limited dataset including the cases and controls and their associated variables that were used in the analysis can be made available for researchers upon request to the corresponding author of this study.
